The management of locally advanced cervical carcinoma in a pilot proton beam facility. To review the first nine patients treated with a pilot proton beam facility for locally advanced cervical carcinoma. We reviewed all patients treated with a proton beam between January 2000 and May 2001. The proton beam facility consists of four synchrotrons. A dedicated thermoplastic shell for the body was manufactured by the facility. Patients were treated with proton beams of 200 MeV, 213 MeV, 230 MeV and 250 MeV, and delivered a total dose of 76-80 Gray equivalents in 8-10 fractions. Six patients had stage IB2 disease, one patient had stage IIA1 disease and two patients had stage IIB1 disease. One patient had received two courses of brachytherapy previously. Four patients received brachytherapy immediately after the irradiation. The remaining five patients were irradiated without brachytherapy. Acute skin toxicity was minimal. With a median follow-up of 21 months, there were three local recurrences, two distant metastases and one death from metastatic disease. Three-year local control was 100%, disease-free survival was 83%, and overall survival was 100%. Despite the small number of patients treated, these data suggest that proton beam irradiation is a safe and effective modality for the treatment of locally advanced cervical carcinoma.

Q: Set viewport for monochrome image I'm trying to set the viewport for this 82157476af
